Lubbock, TX****Abstract**

A project to characterize cotton gin emissions in terms of stack sampling was conducted during the 2008 through 2011 ginning seasons. The impetus behind the project was the urgent need to collect additional cotton gin emissions data to address current regulatory issues. EPA AP-42 emission factors are generally assigned a rating that is used to assess the quality of the data being referenced. The ratings can range from A (Excellent) to E (Poor). EPA current PM<sub>10</sub> emission factor quality ratings for cotton gins are extremely low. Cotton gins received these low ratings because the data was collected almost exclusively from a single geographical region. The objective for this study was to collect additional PM<sub>10</sub> emission factor data for cotton gin systems in regions across the cotton belt based on the EPA approved stack sampling methodologies: Other Test Method 27; Method 201A; and a method that uses Method 17 concentrations multiplied by the percent less than 10 microns determined by the particle size analysis of the Method 17 filter and wash retrieved from each run. Emission factors were developed for 17 different ginning systems including: unloading, 1<sup>st</sup> stage seed-cotton cleaning, 2<sup>nd</sup> stage seed-cotton cleaning, 3<sup>rd</sup> stage seed-cotton cleaning, overflow, 1<sup>st</sup> stage lint cleaning, 2<sup>nd</sup> stage lint cleaning, combined lint cleaning, cyclone robber, 1<sup>st</sup> stage mote, 2<sup>nd</sup> stage mote, combined mote, mote cyclone robber, mote cleaner, mote trash, battery condenser and master trash. Results showed discrepancies between the various methods (Figure 1). These discrepancies were attributed to the cotton fibers and large particles in the exhaust stream impacting the performance of the PM<sub>10</sub> sizing cyclone. Figure 2 compares the average of the EPA stack sampling methodologies, Method 17 and particle size method, and AP-42 emission factor estimates. Combining the measured emission factors for systems that represent a typical gin in AP-42 (Table 1), the typical AP-42 gin PM<sub>10</sub> emission factor based on EPA approved methodologies was 0.987 lb/bale; about 20% higher than the current AP-42 value of 0.817 lb/bale. If the test results were merged with AP-42, in most cases more than tripling the size of the dataset, the merged PM<sub>10</sub> emission factor for the typical AP-42 gin would be 0.926 lb/bale; about 13% higher than the current AP-42 value. In Table 2 the PM<sub>10</sub> emission factors based multiplying the Method 17 concentrations by the percent less than 10 microns obtained from the particle size analysis was compared to emission factors obtained from Method 201A and OTM27 and current AP-42 values for a typical gin. The Method 17 and particle size analysis PM<sub>10</sub> emission factor for a typical gin was 0.66 lb/bale; about 33% less than the emission factor determined from Method 201A and OTM27 and about 20% lower than current AP-42 emission factor estimates. These substantial differences were attributed to the cotton fiber and larger particles impacting the PM<sub>10</sub> sizing cyclone. Additional information can be found in technical reports at <http://buser.bioen.okstate.edu/air-quality/national-cotton-gin-technical-reports>.

Figure 1. Average measured  $PM_{10}$  emission factors from EPA Method 17 multiplied by the percent less than 10 microns from the particle size analysis, Method 201A with only the  $PM_{10}$  sizing cyclone, and Method 201A with both the  $PM_{10}$  and  $PM_{2.5}$  sizing cyclones.

Figure 2. Average measured PM<sub>10</sub> emission factors compared to EPA AP-42 emission factor averages (horizontal, red bars) and ranges (vertical, red error bars).

Table 1. Average measured PM<sub>10</sub> emission factors from EPA approved stack sampling methodologies compared and merged with EPA AP-42 emission factors.
